Module 1: The Observatory

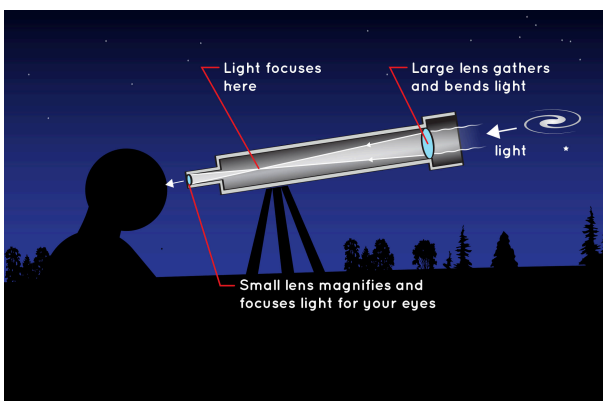

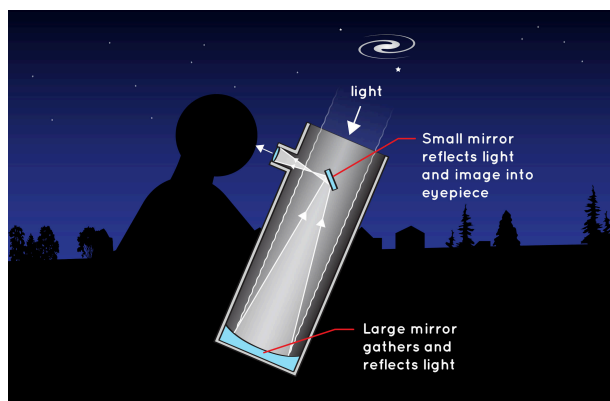

The **Allan I. Carswell Observatory** at York University is a powerful tool that helps us explore the universe from right here on Earth. Using advanced telescopes and imaging technology, it allows astronomers to capture stunning images of planets, stars, and distant galaxies. In this module, we'll dive into how the observatory works, how it collects and processes images, and why observatories are essential for understanding our universe. We'll also discuss important topics like light pollution, telescope technology, and the challenges of space observation. Get ready to see space like never before!

The Allan I. Carswell Observatory

The **Allan I. Carswell Observatory** at York University in Toronto houses Canada's largest on-campus telescope, featuring a 1-meter primary mirror. This telescope uses a reflecting design, where light from celestial objects enters the telescope and hits a large curved mirror at the back. This mirror reflects and focuses the light toward a smaller mirror, which then directs it to cameras or eyepieces for observation. This setup allows astronomers to capture clear images of distant stars and galaxies. Reflecting telescopes are preferred because mirrors can be made larger than lenses, enabling them to gather more light and provide detailed views of the universe.

The **Carswell Observatory** currently houses 3 telescopes:

1. 40 cm
2. 60 cm
3. 1 meter (The largest on campus telescope)

Short Answer Questions

Why is there a limit to what we can see with the naked eye, and how do telescopes help overcome this limitation?

What is the main difference between a refracting telescope and a reflecting telescope in how they gather and focus light?

Why do larger refracting telescopes struggle with light loss, and how does the design of reflecting telescopes solve this problem?

Date: _____

Name: _____

Class: _____

What is atmospheric distortion, and how do astronomers try to minimize its effects when using ground-based telescopes?

Why are telescopes like the Hubble Space Telescope placed in space rather than on Earth, and what advantage does this give them?

Multiple Choice

1. Why do stars appear to twinkle when viewed from Earth?

- A. They are constantly changing brightness
- B. Earth's atmosphere distorts the light coming from stars
- C. The stars are moving rapidly in space

Date: _____

Name: _____

Class: _____

D. Light from the Sun interferes with their brightness

2. What is the main function of the objective lens or mirror in a telescope?

- A. To magnify the image
- B. To bend the light towards the eyepiece
- C. To gather and focus light
- D. To color-correct the image

3. Why are most research telescopes placed on mountaintops?

- A. To be closer to the stars
- B. To reduce the effects of atmospheric distortion
- C. Because the air is colder and helps with imaging
- D. To prevent interference from earthquakes

4. Which of the following is an advantage of space telescopes like Hubble?

- A. They are closer to the stars
- B. They avoid the distortions caused by Earth's atmosphere
- C. They are easier to repair and maintain
- D. They can zoom in more than ground-based telescopes

5. Why is it easier to make a large mirror than a large lens for telescopes?

- A. Mirrors are lighter and do not need to be perfectly shaped
 - B. Large lenses tend to lose light and are harder to support
 - C. Glass for mirrors is cheaper than glass for lenses
 - D. Lenses break more easily than mirrors
-

True or False

Answer the following True and False questions. If you answer False explain your reasoning and correct the False statement.

- 1. True or False: The first telescope was a reflecting telescope that used mirrors.**

- 2. True or False: A concave mirror is used in reflecting telescopes to collect light.**

- 3. True or False: The larger the objective lens or mirror, the more light a telescope can collect. True**

- 4. True or False: All telescopes are affected by Earth's atmosphere, no matter where they are placed.**

Date: _____

Name: _____

Class: _____

- 5. True or False: The Hubble Space Telescope orbits the Moon to get a clearer view of space.**

Date: _____

Name: _____

Class: _____
